
Cells: z of the set against genes permuted within identity and expression bins of the tissue (color clipped at ±8); * $q < 0.05$; gray cell, fewer than 15 genes. Right: q, recurrence across tissues; S_g and profile correlation, tissues with the set above (↑) and below (↓); π and dN/dS, mean z over tissues. Gray type: not recurrent under every control (q), on that readout (S_g, profile correlation), or |mean z| below 1.96 (π, dN/dS).
